APPENDIX A

HAZARD IDENTIFICATION, RISK ASSESSMENT AND VULNERABILITY

FLOOD

Flood plains are relatively flat lands that border streams and rivers that are normally dry, but are covered with water during floods. The susceptibility of a stream to flooding is dependent upon several different variables. Among these are topography, ground saturation, rainfall intensity and duration, soil types, drainage, drainage patterns of streams, and vegetative cover. A large amount of rainfall over a short time period can result in flash flood conditions. A small amount of rain can also result in floods where the soil is saturated from a previous wet period or if rain is concentrated in an area of impermeable surfaces such as large parking lots, paved roadways, etc. Topography and ground cover are contributing factors for floods where water runoff is greater in areas with steep slopes and little or no vegetation. The severity of a flood is usually measured in terms of depth of flooding.

Flooding occurs when the volume of water exceeds the ability of a water body (stream, river, or lake) to contain it within its normal banks. Floodplains serve three major purposes: Natural water storage and conveyance, water quality maintenance, and groundwater recharge. These three purposes are greatly inhibited when floodplains are misused or abused through improper an unsuitable land development. For example, if floodplains are filled to construct a building, valuable water storage and recharge areas are lost. This causes unnecessary flooding in previously dry areas and can damage buildings and other structures.

Severe flooding within McDuffie County is relatively infrequent. The have been six documented flood events in the county in the past 20 years. These flooding events have caused nearly \$30,000 in damage. The hazard frequency table indicates there is a 30 percent chance of an annual flooding events in the county.

Based on tax data, parcel and flood maps, all or a portion of 1,002 known structures/properties valued at approximately \$100 million and a population of 412 are located in known floodplains. The committee identified specific mitigation goals, objectives and action items related to flooding, which can be found in Chapter III, Section I.

	/1995 Flash Flood /2001 Flash Flood	0			Flood conditions were reported beginning at 1:00 am and ending at 7:00 am, resulting in 18 hours of flash flooding.
	Flood /2001 Flash				beginning at 1:00 am and ending at 7:00 am, resulting in 18 hours of flash flooding.
NORTH PORTION 6/13	•	0	0	0	
				U	Sheriff reported water moving over Folly Lake Bridge and on Stagecoach road.
THOMSON 9/10	/2008 Flash Flood	0	0	10000	DOT reported secondary dirt roads washed out from flash flooding that will have to be re-excavated.
BONEVILLE 1/24	/2010 Flash Flood	0	0	20000	Sheriff reported flooding at apartment complex with up to a foot of water in several apartments.
Countywide 12/29	/2015 Flood	0	0	0	Rutted roads and swollen creeks and ponds were the aftermath of 4.81 inches of rain that fell in Thomson-McDuffie County between Dec. 21 and Dec. 28.
Thomson 12/30	/2016 Flash Flood	0	0		According to WTHO-FM, the Thomson area has received 7.11" from Dec. 21 through the morning of Dec. 31. Throughout the day on Dec. 30, the radio station measured 1.52 inches. Roads including First Avenue, Manassass Drive, A Street and Sill Street were affected by the flooding and standing water.
Countywide 9/11	/2017 Heavy Rain	0	0	0	AWOS unit at Thomson McDuffie Co Airport measured a total of 5.37 inches of rain.

DROUGHT

Drought is a normal, recurrent feature of climate consisting of a deficiency of precipitation over an extended period of time (usually a season or more). This deficiency results in a water shortage for some social or environmental sector. Drought should be judged relative to some long-term average condition of balance between precipitation and evapotranspiration in a particular area that is considered "normal." Drought should not be viewed as only a natural hazard because the demand people place of water supply affects perceptions of drought conditions. The impacts of drought are vast, including limited water supplies in urban areas to insufficient water for farmland.

Drought is not spatially defined and equally affects the entire planning area. Droughts do not have the immediate effects of other natural hazards, but sustained drought can cause severe economic stress to not only the agricultural interests in McDuffie County, but to the entire State of Georgia. The potential negative effects of sustained drought are numerous. Based on a 20-year cycle hazard history there is a 120 percent chance of an annual drought event in McDuffie County. In addition to an increased threat of wildfires, drought can affect private wells, municipal and industrial water supplies, stream-water quality, water recreation facilities, hydropower generation, as well as agricultural and forest resources.

In McDuffie County there are 2,972 agricultural/forestry properties valued at approximately \$317 million and include 6,381 heads of cattle and an estimated population of 280 that have the greatest potential to be damaged by drought. There is a population of 21,455 and approximately 32,429 structures/properties in the county with a value of nearly \$1.9 billion, which could be affected if wildfires break out due to drought conditions. Drought mitigation goals and objectives are in Chapter III, Section III.

WILDFIRE

A wildfire is any uncontrolled fire occurring on undeveloped land that needs fire suppression. The potential for wildfire is influenced by three factors: the presence of fuel, the area's topography and air mass. There are three different classes of wildland fires. A surface fire is the most common type and burns along the floor of a forest, moving slowly and killing or damaging trees. A ground fire is usually started by lightning and burns on or below the forest floor. Crown fires spread rapidly by wind and move quickly by jumping along the tops of trees. Wildfires are usually signaled by dense smoke that fills the area for miles around. Wildfires by lightning have a very strong probability of occurring during drought conditions. Drought conditions make natural fuels (grass, brush, trees, dead vegetation) more fire-prone.

McDuffie County's consist of 266 square miles with 8.9 of these miles being water. The county is comprised of 170,373 acres with 37,989 (22.3 percent) acres dedicated to agricultural and 90,141 (54.2 percent) acres dedicated to forestry. Given the right weather conditions and variables, wildfire due to natural causes creates a potential threat to the lives and property of residents in the planning area. According to Georgia Forestry data, from 1957 to 2018, there have been 2,272 fire events burning a total of 11,131 acres. Based on a 20-year hazard cycle there is a 3,695 percent chance of an annual wildfire due to a natural hazard event.

The GMIS has five facilities with a hazard score of four (high), 40 with a hazard score of three (moderate), seven with a hazard score of two (low), and 14 with a hazard score of one. The remaining ten critical facilities have a hazard score of zero. The 66 facilities with a hazard score greater than zero have an estimated potential loss of more than \$113 million. The replacement value for all critical facilities is approximately \$115,474,055.

ACRES BURNED

TORNADO

A tornado is a violent windstorm characterized by a twisting, funnel-shaped cloud. It is spawned by a thunderstorm or the result of a hurricane and is produced when cool air overrides a layer of warm air, forcing the warm air to rise rapidly. Tornados are among the most unpredictable and destructive of weather phenomena and can strike at any time of the year if the essential conditions are present. The damage from a tornado is a result of the high wind velocity and wind-blown debris. The positions of the subtropical and polar jet streams often are conducive to the formation of storms in the Gulf region. The table below shows the original Fujita Scale and the Enhanced Fujita Scale (in use since 2007) to rate the intensity of a tornado by examining the damage caused by the tornado after it has passed over a manmade structure.

Tornados do not touch down frequently; however, the unpredictability and the potential for excessive damage caused by tornados makes it imperative that mitigation measures identified in this plan receive full consideration. Based on historical data, there have been nine reported tornados in the planning area. There have not been any reports of tornadoes since the last update. Since 1950, there has been approximately \$130,000 in property damage and crop damage as well as three deaths from tornadoes. Tornados tend to strike in somewhat random fashion, making the task of calculating a recurrence interval extremely difficult. There is a 25 percent annual chance of a tornado event at for McDuffie County as a whole.

location	Date	Fvent	Scale	Deaths	Iniuries	Property Damage	Cron Damage	Description
MCDUFFIE CO.	3/20/1875	Tornado	*	*	*	*	*	25 people were killed and 65 were injured in a tornado that formed Hancock County, moved across McDuffie County and dissipated in Columbia County.
MCDUFFIE CO.	5/24/1955	Tornado	F0	3	0	2500	0	
MCDUFFIE CO./THOMSON	4/5/1957	Tornado	F2	0	0	*	*	
MCDUFFIE CO.	2/2/1973	Tornado	F1	0	0	2500	0	
THOMSON	1/13/2005	Tornado	FO	0	0	0	0	Storm Survey found an F0 broke trees in half at the intersection of I-20 and White Oak road.
THOMSON	3/1/2007	Tornado	EF2	0	0	0	0	An EF2 started in Warren county and moved through McDuffie county taking down numerous trees and powerlines. The twister moved along hwy 278 to Thomson then along hwy 150 to I-20. Several vehicles were totaled and many homes and a private school had moderate damage. Ground survey found a damage path of 9 miles in McDuffie county but an areal survey found the total length to be 15 miles. There were no injuries or deaths.
MCDUFFIE CO.	3/15/2008	Tornado	EF0	0	0	0	0	Storm survey found an FO started in McDuffie county taking down many trees and continued into Columbia county.
MCDUFFIE CO.	2/18/2009	Tornado	EFO	0	0	0	50000	Storm survey found the tornado path coming out of Wilkes county into McDuffie county. Only trees were in the path of the tornado with many being taken down just south of the lakeshore.

								* Unknown
	77,000.00 \$ 50,000.00	\$ 77,000.00	0	3				
Dispatch reported trees down, some on vehicles, on Moose Club road. NWS damage survey also found and minor damage to several homes.	0	72000	0	0	EF0	Tornado	4/10/2009	MCDUFFIE CO.

TROPICAL STORMS

Tropical storms begin as tropical depressions over warm oceanic water, then develop into tropical cyclones. A tropical cyclone life span can last from a few hours to close to three weeks. Most tropical cyclones last approximately five to ten days. If the winds are under or up to 39 mph, it is a tropical depression. If winds speeds are between 39 to 73 mph, it is considered a tropical storm. Any storm with over 74 mph wind speed is called a hurricane. As a rule, hurricanes occur in the western Atlantic Ocean when warm, humid conditions are prevailing. Hurricanes are usually accompanied by excessive rain, thunder and lightning. When hurricanes make landfall, they typically slow down. Unfortunately, at that time, another danger often appears – tornados. A storm surge, which is an abnormal rise in water levels in a coastal area, usually occurs with tropical storms. McDuffie County is not likely to experience a hurricane or storm surges.

In the last 70 years there have been 19 tropical storms that have affected the county with heavy rainfall and strong wind. Although there has been no property or crop damage, roads have been flooded and downed trees have caused widespread power outages across the county. Based on a 20-year hazard frequency cycle, there is a 75% chance of an annual tropical storm event for all jurisdictions.

SEVERE THUNDERSTORM (Wind, Hail, & Lightning)

The first severe weather event, thunderstorm winds, can cause death, injury, power outages, property damage, disrupt telephone service, and severely affect radio communications which may seriously impair the emergency management capabilities of the affected jurisdictions. Thunderstorm winds arise as a result from convection (with or without lightning), with speeds of at least 50 knots (58 mph), or winds of any speed producing a fatality, injury, or damage. Severe thunderstorms develop powerful updrafts and downdrafts. An updraft of warm, moist air helps to fuel a towering cumulonimbus cloud reaching tens of thousands of feet into the atmosphere. A downdraft of relatively cool, dense air develops as precipitation begins to fall through the cloud. Winds in the downdraft can reach in excess of 100 miles per hour. When the downdraft reaches the ground, it spreads out forming a gust front: the strong wind that kicks up just before the storm hits. As the thunderstorm moves through the area, the full force of the downdraft in a severe thunderstorm can be felt as horizontal, straight-line winds with speeds well over 50 miles per hour. Straight-line winds are often responsible for most of the damage associated with a severe thunderstorm. Damaging straight-line winds occur over a range of scales. At one extreme, a severe single-cell thunderstorm may cause localized damage from a microburst, a severe downdraft extending not more than about two miles across. In contrast, a powerful thunderstorm complex that develops as a squall line can produce damaging winds that carve a path as much as 100 miles wide and 500 miles long.

The second severe weather event is hail. Hailstones are created when strong rising currents of air called updrafts carry water droplets high into the upper reaches of thunderstorms where they freeze. These frozen water droplets fall back toward the earth in downdrafts. In their descent, these frozen droplets bump into and coalesce with unfrozen water droplets and are then carried back up high within the storm where they refreeze into larger frozen drops. This cycle may repeat itself several times until the frozen water droplets become so large and heavy that the updraft can no longer support their weight. Eventually, the frozen water droplets fall back to earth as hailstones.

Hail can also be a destructive aspect of severe thunderstorms. Hail causes more monetary loss than any other type of thunderstorm-spawned severe weather in the United States, annually producing about one billion dollars in crop damage. Storms that produce hailstones only the size of a dime can produce dents in the tops of vehicles, damage roofs, break windows and cause significant injury or even death.

The third type of severe weather events is lightning. Lightning is a giant spark of electricity in the atmosphere between clouds, the air, or the ground. In the early stages of development, air acts as an insulator between the positive and negative charges in the cloud and between the cloud and the ground. When the opposite charges build up enough, this insulating capacity of the air breaks down and there is a rapid discharge of electricity that we know as lightning. The flash of lightning temporarily equalizes the charged regions in the atmosphere until the opposite charges build up again.

WINTER STORMS

Southeastern snow or ice storms often form when an area of low pressure moves eastward across the northern Gulf of Mexico. To produce a significant winter storm in the south, not only must temperatures be cold enough, but there must also be enough moisture in the atmosphere to produce adequate precipitation. A major winter storm can last for several days and be accompanied by ice and freezing rain, high winds, heavy snowfall, and cold temperatures. These conditions can make driving very dangerous, as well as bring down trees and power lines.

There have been 28 winter storm events recorded in the county over the last 70 years with no property damaged reported. Damage from these events totals over \$360 thousand. There is a 45 percent chance of an annual winter storm event. Winter storms can be more accurately predicted than most other natural hazards, making it possible to give advance warning to communities. The National Weather Service issues winter storm warnings and advisories as these storms make their way south. Given the infrequency of these types of storms, southern communities are still not properly equipped to sustain the damage and destruction caused by severe winter storms. To summarize, there are approximately 32,429 structures/properties in the county totaling nearly \$1.9 billion with a population of 21,455. The committee recognized the dangers posed by winter storms and identified specific mitigation actions in Chapter III, Section VI.

and snow accumulations were 3 to 5 inches.
